### Lecture 21: Quasi-Random Graphs (4)

Wed 13 Oct 2021 10:17

We complete the proof from last time. Recall our lemma that for orthonormal basis containing  $x_1$  we have  $|x_1 - j|_2 = o(1)$ . We proceed

*Proof.* WLOG assume  $G$  to be a random graph of even order and  $|S| = \frac{n}{2}$ . Then,

we define a vector  $\vec{S}$  with  $s_i = \begin{cases} \frac{1}{\sqrt{n}}, & i \in S \\ -\frac{1}{\sqrt{n}}, & i \in V \setminus S \end{cases}$  It is clear  $|S|_2 = 1$  and we see

$$\langle S, j \rangle = \underbrace{\frac{1}{\sqrt{n}} \cdot \frac{1}{\sqrt{n}}}_{\frac{n}{2} \text{ times}} + \underbrace{\frac{1}{-\sqrt{n}} \cdot \frac{1}{\sqrt{n}}}_{\frac{n}{2} \text{ times}} = 0.$$

Then, we note  $\langle S, x_1 \rangle = \langle S, j \rangle + \langle S, x_1 - j \rangle = \langle S, x_1 - j \rangle$  and applying cauchy-shwartz yields

$$\langle S, x_1 \rangle = \langle S, x_1 - j \rangle \leq |S|_2 |x_1 - j|_2 = 1 \cdot o(1) = o(1).$$

Now, define  $Z = S - \langle S, x_1 \rangle x_1$ . Then, we see

$$\langle Z, x_1 \rangle = \langle S, x_1 \rangle - \langle S, x_1 \rangle |x_1|_2^2 = 0.$$

So,  $Z$  is orthogonal to  $x_1$ . Hence, there is a  $n - 1$  dimensional space,  $M$ , generated by  $x_2, \dots, x_n$  with eigenvalues  $\lambda_2, \dots, \lambda_n$  with largest eigenvalue  $\max\{\lambda_2, |\lambda_n|\}$ .

Then, we find by the rayleigh quotient that  $|\langle Ay, y \rangle| \leq \lambda_1(M) |y|_2^2 = \sigma_2 |y|_2^2$  for all  $y \in M$ . Similarly, we find

$$\lambda_n |y|_2^2 \leq \langle Ay, y \rangle \leq \lambda_2 |y|_2^2$$

for all  $y \in M$ . From this we get  $\lambda_n |Z|_2^2 |\langle AZ, Z \rangle| \leq \lambda_2 |Z|_2^2$ , and recalling  $|Z|_2 \leq |S|_2 + |\langle S, x_1 \rangle| |x_1|_2 = 1 + o(1) \leq 2$

$$|\langle AZ, Z \rangle| \leq \sigma_2 |Z|_2^2 \leq \sigma_2 |2|_2^2 = 4\sigma_2 = o(n).$$

Finally, we see

$$\begin{aligned}
\langle AS, S \rangle &= \langle A(Z + \langle S, x_1 \rangle x_1), Z + \langle S, x_1 \rangle x_1 \rangle \\
&= \underbrace{\langle AZ, Z \rangle}_{o(n)} + \underbrace{\langle S, x_1 \rangle \langle AZ, x_1 \rangle}_{o(1)} + \underbrace{\langle S, x_1 \rangle \langle Ax_1, Z \rangle}_{=0} + \underbrace{\langle S, x_1 \rangle \langle Ax_1, x_1 \rangle}_{o(1)} \\
&= o(n) + \langle S, x_1 \rangle^2 \langle Ax_1, x_1 \rangle \\
&= o(n) + \lambda_1 \\
&= o(n^2)
\end{aligned}$$

Recall we also know

$$\langle AS, S \rangle = 2e(S) + 2e(G \setminus S) - 2e(S, G \setminus S).$$

and  $2e(S) + 2e(G \setminus S) + 2e(S, G \setminus S) = e(G) \geq \frac{1}{4}n^2 + o(n^2)$ . Then, adding and dividing yields these identities yields  $e(S) + e(G \setminus S) = \frac{n^2}{8} + o(n^2)$ . Furthermore,  $\sum_{i \in S} d_i = \frac{n^2}{4} + o(n^2) = 2e(S) + e(S, G \setminus S)$  and  $\sum_{i \in G \setminus S} d_i = \frac{n^2}{4} + o(n^2) = 2e(G \setminus S) + e(S, G \setminus S)$ . Adding all of the identities thus far yields that  $2e(S) - 2e(G \setminus S) = o(n^2)$ , hence  $e(S) = \frac{1}{16}n^2 + o(n^2)$ .  $\square$

We are nearing the end of quasi-random graphs, but note we have always assumed a quasi-random graph to have density  $\frac{1}{2}$ . These properties are easily generalized to one of density  $p$ . We list the generalized properties.

**Definition 0.1.** 1.  $(P_2)$ . A graph is  $P_2$  if

- $e(G) \geq \frac{pn^2}{2} + o(n^2)$
- $\#CW_4 \leq p^4 n^4 + o(n^4)$ .

2.  $(P_3)$ . A graph is  $P_3$  if

- $e(G) \geq \frac{pn^2}{2} + o(n^2)$
- $\lambda_1(G) = pn + o(n)$
- $\sigma_2(G) = o(n)$ .

3.  $(P_7)$ . A graph is  $P_7$  if

- $\sum_{1 \leq i, j \leq n} |\hat{d}_{ij} - p^2 n| = o(n^2)$ .

## Lecture 22

Fri 15 Oct 2021 10:24

**Recall.** A quasi-random graph could be characterized as one with a gray adjacency matrix.

**Example.** A paley graph of order  $q$  is quasi-random.  
For this graph  $G$ , we see

- $e(G) = \frac{1}{2}q \frac{q-1}{2} = \frac{1}{4}q^2 + o(q^2)$ ,

- $\lambda_1(G) = \frac{q-1}{2} = \frac{1}{2}q + o(q)$ , and
- $\sigma_2(G) = \frac{1+\sqrt{q}}{2} = o(q)$ .

Hence,  $G$  is  $P_3$ , so it is quasirandom.

We also have a conference graph  $\text{SRG}(4k+1, 2k, k-1, k)$  has

- $\lambda_1 = 2k = \frac{n}{2} + o(n)$ ,
- $\sigma_2 = \frac{1+\sqrt{n}}{2} = o(n)$ , and
- $e(G) = k(4k+1) = \frac{1}{4}n^2 + o(n^2)$ .

We also have  $K_{n,n}$  and  $cK_n$  are trivially SRG, but not quasi-random. As it turns out these are the only SRG which are not quasi-random.  $\diamond$

**Proposition 0.1.** All nontrivial SRG (not  $K_{n,n}$  or  $cK_n$ ) are quasi-random.

**Remark.** A random graph of order  $n$  is quasi-random with probability 1 as  $n \rightarrow \infty$ .

**Definition 0.2** (Perturbation). Let  $G$  be a quasi-random graph of order  $n$  with adjacency matrix  $A$ . We may perturb  $G$  by choosing a set  $E$  of edges such that  $|E| = o(n^2)$  and deleting them. From this we obtain a graph  $G' = G - E$ . We find  $G'$  is also quasi-random.

*Proof.* Let  $G'$  be the result of perturbing a quasi-random graph  $G$  having adjacency matrix  $A$  and let  $A'$  be the adjacency matrix of  $G'$ . Then, denote  $B$  to be the adjacency matrix containing only the deleted edges. So, we find  $A' = A - B$ . We wish to show  $\lambda(A') = \lambda(A) + o(n)$  and  $\sigma_2(A') = \sigma_2(A) + o(n) = o(n)$ . Now employing Weyl's inequalities:

$$\lambda_i(A) + \inf\{\lambda_i(B) : 1 \leq i \leq n\} \leq \lambda_i(A+B) \leq \lambda_i(A) + \lambda_i(B)$$

yields

$$\lambda_i(A) + \lambda_{\min}(-B) \leq \lambda_i(A') \leq \lambda_i(A) + \lambda_1(-B).$$

We see it suffices to show  $\lambda_{\min}(-B) = o(n)$  and  $\lambda_1(-B) = o(n)$ .

Recall that  $\lambda_1^2(-B) + \dots + \lambda_n^2(-B) = |B|_2^2 = 2|E|$ , hence  $\lambda_1^2(-B) \leq 2|E| = o(n)$  and likewise for  $\lambda_{\min}^2(-B)$ . Hence, we have  $\lambda_i(B) = o(n)$ , so

$$\lambda_1(A) + o(n) \leq \lambda_1(A') \leq \lambda_1(A) + o(n).$$

So,  $\lambda_1(A')$  is desired. Similarly, WLOG we can assume  $\lambda_2(A) = \sigma_2(A)$ , so we see

$$\lambda_2(A) + o(n) \leq \lambda_2(A') \leq \lambda_2(A) + o(n).$$

and as  $\lambda_2(A) = o(n)$  by quasi-randomness, we see  $\lambda_2(A') = \sigma_2(A') = o(n)$ .  $\square$

**Remark.** This also clearly works with addition of  $o(n^2)$  edges (provided they will fit). Furthermore, we can union a quasi-random graph with a graph of sufficiently small order and obtain a quasi-random graph.

**Proposition 0.2.** Let  $G$  be quasi-random with adjacency matrix  $A$  and construct the following matrix

$$J_2 \otimes A = \begin{bmatrix} A & A \\ A & A \end{bmatrix}.$$

Then, the graph  $G'$  obtained from this matrix is the blowup of  $G$ . We see for  $G$  being regular, we have  $G'$  is regular. It turns out  $G'$  is also quasi-random. However, we find  $G$  being SRG does not guarantee  $G'$  to be SRG.
